[Bisphosphonates and bone remodeling: effectiveness in Paget's disease, fibrous dysplasia and osteoporosis.]

[Article in French]

Chapurlat R, Meunier PJ.

Service de Rhumatologie et de Pathologie Osseuse, Hopital
Edouard Herriot, Lyon.

Paget's disease of bone, bone fibrous dysplasia and osteoporosis are characterized by abnormal bone remodeling, and frequently imply intervention of orthopedists. Recent significant medical therapeutics improvements have been obtained with the use of bisphosphonates. These drugs decrease bone remodeling. In Paget's disease, bisphosphonates relieve bone pain, allow lytic areas refilling and decrease complications risk with normal bone formation. In fibrous dysplasia, bone pain is alleviated, osteolytic areas are refilled and cortices are widened. In postmenopausal osteoporosis, bisphosphonates increase bone mineral density, and reduce very significantly the subsequent risk of vertebral, femoral and lower forearm fractures. Bisphosphonates are a breakthrough in Paget's disease of bone, fibrous dysplasia of bone and osteoporosis.
